1972

Towards the mechanisms of Naming Disturbances

A. R. LURIA.

In a series of papers the outstanding psychologist R.C. Oldfield, to whom we pay respect in this issue, discussed one of the most important problem - that of the mechanisms of naming and its disturbances in local brain lesions. It is just this problem we shall dwell in this paper.

During many decades the theory of naming defects and "amnesic aphasia" remained one of the most obscure parts of Neurology.

The classics of Neurological Sciences discussed as a rule the naming defects from the standpoint of a simple approach to the word as an association of cerebral sound complexes with an image of an object. That is why naming of an object was considered to be an evocation of this sound complex and disturbances of naming were ~~regarded~~^{regarded} as special defect of memory traces. This concept has to be fundamentally reconsidered.

1. Naming process and its psychophysiological mechanisms

~~The~~ Modern neurologists singles out two basic mechanisms of the word as a unite of language.

A word designates a certain object, having an immediate significative function; at the same time it includes the object in a system of connections; the last process is known as the coding and it results in a meaning of the word. (1).

According that ~~approximate~~ double function of the word two groups of psychological processes are required to name an object.

Firstly - the subject has to single out some basic cues of the object to be named. That requires a clear ^{image} ~~perception~~ of the object from one side and a well organized acoustic structure of the word used as its name. If one of both conditions are deranged normal naming is disturbed.

The second condition of naming is a preservation of a complex ~~system of~~ coding process, otherwise - a clear selective structure of semantic connections of the word.

As we already mentioned the word is a nucleus of a complex semantic system or a multivariate matrix. Thus the word "inkstead" designates an object dealing with ink (or another color tissue), a container etc.; it evokes a whole code of interrelated objects as well as a situation of writing, drawing ~~at~~ (desk, paper, pen, school etc.); it can evoke as well a series of words with a morphological similarity (ink-stand; cup-board etc.) or even words with a similar phonetic structure. ~~That~~ That is why to find a proper name one has to make a choice between these manifolded connections; in this respect naming requires a decision making.

In cases of simple objects and well integrated names this process ~~is~~ ~~key~~ is well automatized; in cases of unfrquent objects and not too-well automatized names it requires a ~~rather~~ complicated task and sometimes becomes rather difficult. Such cases ~~are~~ were carefully studied during the last decade and the "tip-of-tongue phenomenon" was carefully described (2).

In normal conditions the process of choice does not evoke considerable

difficulties: the ^{high} selectivity of higher nervous processes provides all necessary condition of an adequate finding of the word: ~~the~~ as a rule strong (or significant) traces ^{or connections} are evoked easily whereas weak (or insignificant) traces or connections are easily blocked. This is a result of the "law of force", described by Pavlov as one of the basic laws of the flow of higher nervous processes, as well of the high plasticity of nervous processes which make a high selectivity of the psychological processes possible.

All these conditions are severely affected in pathological states of the brain.

As it was shown by Pavlov and his school - pathological states of the cortex result in so-called "inhibitory" states. Strong (or important) stimuli or their traces begin to evoke the same re. actions as weak (or insignificant) ones, and this equalization of excitability results in a breakdown of the selectivity of mental processes. When the pathological state becomes more massive - ~~weak~~ ^(or insignificant) stimuli evoke even stronger reactions than the strong (or significant) ones and the selectivity of psychological processes with a dominance of the most important connections ~~[is fully destroyed]~~ ^[is destroyed] which is needed for a ^{well} organized naming process is fully destroyed (3).

Similar changes are observed in the plasticity of nervous processes: an easy blocking of former links of psychological process, which is easy for a normal plasticity of the nervous system, becomes severely deranged in pathological states, and a pathological inertia of the former traces (or perseveration) can be observed. That hinders the normal selectivity of psychological processes as well, and the naming process can acquire new difficulties. (4)

Of a highest importance is the fact that these pathological states can have as well a general character (which is typical for disorders of the deep parts of the brain), as well as a partial or regional character - when the pathological process is situated in the cortical zones of the brain. In these last cases a loss of selectivity of psychological processes can be limited by certain specific forms of functions, - and just these cases are of the highest importance for the appearance of special kinds of naming defects.

2. Basic Types of naming defects and "amnesic aphasia"

There are different ~~many~~ defects underlying naming disturbances in differently localized brain lesions.

At least two groups of such disturbances can be mentioned. The first group has as a ground defects of selectivity of sensory-motor (modality-specific) processes and the process of naming is disturbed in its input or output. In the second group disturbances of selectivity are of a higher level and the semantic organization of the process of choice of the proper word can become highly difficult.

Let us discuss these basic groups separately.

At the very beginning of the study of aphasia ⁽⁵⁾ ⁽⁶⁾ ⁽⁷⁾ ⁽⁸⁾ ⁽⁹⁾ ⁽¹⁰⁾ ⁽¹¹⁾ ⁽¹²⁾ ⁽¹³⁾ ⁽¹⁴⁾ ⁽¹⁵⁾ ⁽¹⁶⁾ ⁽¹⁷⁾ ⁽¹⁸⁾ ⁽¹⁹⁾ ⁽²⁰⁾ ⁽²¹⁾ ⁽²²⁾ ⁽²³⁾ ⁽²⁴⁾ ⁽²⁵⁾ ⁽²⁶⁾ ⁽²⁷⁾ ⁽²⁸⁾ ⁽²⁹⁾ ⁽³⁰⁾ ⁽³¹⁾ ⁽³²⁾ ⁽³³⁾ ⁽³⁴⁾ ⁽³⁵⁾ ⁽³⁶⁾ idea was adequate for some forms of naming disturbances observed in cases of so-called sensory (or acoustico-gnostic) aphasia. Further investigations (7, 8, 9) showed that even these disturbances were of a much more complicated type and that the underlying mechanisms are not simple "trace decay", but that they are rather are some basic disorders of phonematic organization of the word perception. The loss of selectivity in these cases are seen in a strong loss of selectivity of the "correlated" phonemes which result in a certain "alienation of word meaning" which is typical for sensory aphasia. It is obvious that patients of this group become unable to find proper words because the choice of selective phonemes is disorganized, and different phonemes are evoked with equal probability and paraphrasias appear. It is obvious as well that every attempt to help the patient, giving him the first syllable of the word does not bring to any results. That is the picture of the sensory disturbances in word finding we have ~~at~~ described elsewhere (10, 11)

The second form of naming disturbances included in the first basic group appear in ~~cases of the loss of selectivity in~~ ^{pathological states of the left} post central (kinesthetic) parts of the ~~left hemisphere~~ ^{cortex} associated with a ~~pathological~~ loss of selectivity in the articulatory system. In these cases selectivity of appearance of the needed "articulemes" is highly deranged, different (kinesthetically similar) articulemes (such as palato-labial l-n-d) are evoked with equal probability, and naming becomes difficult - in these cases for a different reasons. These cases are sometimes called "phonematic desintegration of speech" of the French authors (12, 13, 14) and the disorders underlying naming defects are different.

The second basic group of naming defects was described as a "primarily" or "pure" amnesic aphasia by ~~K. Goldstein (15, 16), K. Head (17) et al.~~ ~~K. Goldstein (15, 16), K. Head (17) et al.~~

In this group lesions of the tertiary (parieto-occipital) parts of the left hemispheric ^{and} speech areas do not result in sensory or motor defects and the ~~input~~ ^{input and} ~~output~~ ^{output} of speech processes ~~is~~ ^{are} preserved. The basic

symptoms in all these cases is a disturbance of finding proper names of objects. Patients preserve their fluent speech with excellent prosodic, intonational and syntactic structure, but they are unable to recall the words needed and either show a total inability to name objects or begin to try to find the word needed and instead of adequate naming of the object give a series of ^(18, 19, 20) paraphrasias which are mostly of a "verbal" character. The "tip of tongue phenomenon" is easily observed in these cases, and instead of naming "a pencil" the patient can say "Oh... a boy... Oh, no... a school... Oh, no... to write... it is necessary for writing a letter..." etc. Sometimes they replace the word needed by another word which is similar in strict morphological structure (saying "cup-board" instead of "ink-stand") etc. It is very typical that a secret help -

The word ~~does~~ provides a good effect and the patient remembers the word adequate word very easily. That is why this type of an "amnesic aphasia" was considered ~~of it~~ as a pure type of that disorder.

Two hypotheses were proposed to explain this basic symptom.

One part of the authors tried to understand these defects as a result of a partial loss of verbal memory traces; the second - as a disturbance of an intellectual defect - a disturbance of an abstract, "categorical" attitude.

Both hypotheses are hardly acceptable.

Observations of the verbal behavior of patients of this group show that the defects observed are not a loss of the word needed but rather a defect of choice among a whole complex of words which are coming in mind of the patient, an impossibility to select the word needed from a great amount of designations which are associated with the adequate word acoustically, morphologically or semantically and which are evoked in equal probability. Very often patients of this group can evoke abstract and too generalized designations (as such as "a bird", "a flying animal" instead of "a sparrow" or as "an animal", "a house animal" instead of "a kitten"). No loss of words or abstract attitude, but rather a struggle of a large amount of different designations take place alternative take place and the patient becomes unable to make a proper decision.

Careful analysis shows that at least two defects can be singled out as mechanisms underlying this defect: symptom.

One is of an optico gnostic, the second - of a pure semantic type.

The first of these mechanisms was carefully studied by our collaborator - Dr. L.S. Tsvetkova.

(such as: "oh that is the thing I have to you for writing" etc.)
Careful studies show that this type of naming defects can be of two types, the first being a result of gnostic, the second - of pure semantic type.

As it was shown by L.S. Tsvetkova and her collaborators (21, 22) patients with lesion of the left parieto-occipital zones of the cortex and to with troubles of naming have as well some slight defects of optical images of the objects. If they are given an uncomplete scheme of an animal and asked to accomplish this scheme so that the drawing will be the image of a cock or a hen, a rabbit or a cat, - they are unable to do it, and the process of singling out the optical cues decisive for such a task is severely impaired. As it was shown - the same patients are unable to decide whether the stylized schematic drawing given is that of a cat or a rabbit (21).

if it is seen that

Their defect of visual imagery due to equalization of all visual cues result in a difficulty to single out the decisive optical image of the object, and it is the defect of well organized optical image, which, according to modern views (23) hinders in these patients is necessary for the process of decision-making (23) - results in disturbances of the naming process, which in these cases suffers from its optical, object-associated base) which is disrupted in these cases.

thus - in this first group of patients naming defects can be a result of a slight deterioration of optical gnosis which is an important basis of every object naming.

In the second group of patients with naming defects optical gnosis can be preserved but a severe deterioration of the higher processes of involved in naming - the finding of the proper word.

As we have already mentioned not a loss but of the proper word but rather a struggle between a complex of alternative designations which are evoked with equal probability is observed in these cases. These probabilities can be of different kinds. Sometimes designations of single properties are evoked, and the patient trying to find the name word "kitten" is saying: "this small thing...", "this furrow...", "it deals with mouse", "it plays", "it has claws...". Sometimes a word with a phonetic or morphological similarity (as "bitten".... "kitten" etc.) is reproduced, - and this amount of designations evoked with equal probability hinders to find the word needed.

These cases are observed in pathological states of the tertiary zones of the posterior parts of speech areas (temporo-parietal associative zones), and it can be supposed that a certain stage of equalization of the excitability of the whole net of connections

which are evoked by the complex semantic matrix of the word is the basic physiological defect underlying this kind of naming troubles of object naming.

Of course this hypothesis has to be proven and special series of experiments are needed to ~~make~~ decide whether the mechanism we mentioned is probable.

We have to make at least step and to mention one more form of the naming defects which appear in local ~~brain~~ lesions of the ~~the~~ human cortex.

All types of naming disturbances we described are associated with some hierarchical organization of codes (phonetic, articulatory or semantic). They all appear in lesions of the posterior parts of the speech areas and they all are of a "paradigmatic" type.

A fully different kind of defects is seen in lesions of the anterior parts of the speech zones.

In these kinds the ~~process~~ of the paradigmatic organization of the speech processes ~~is~~ remains preserved and no defects ^{neither} in singling out cues needed nor in their organization ~~of the~~ in a system of codes is seen. Therefore - these patients have no "similarity defects" ~~(R. H. H. which was carefully described by R. Jakobson)~~ ~~and~~ and no defects of immediate naming of objects is observed.

The defects observed in these cases are of a ~~rather~~ different types: ~~the~~ fluent sequential organization of speech processes becomes defective, ~~and~~ "syntagmatic" organization of propositional speech i.e. of construction of fluent sentences, is observed (24) ~~and~~ ~~sometimes~~ (7, 24, 25). That is why symptoms difficulties of naming can ~~be~~ appear, but in these cases disturbances of naming ~~can~~ appear in the fluent, syntagmatically organized speech, and ~~don't~~ are not observed in immediate naming of isolated objects. We do not yet know the neuropsychological mechanisms underlying these defects and we can only suppose that they are closely associated with a ~~good~~ derangement of the inner speech which is an important ~~its~~ mechanisms for a generating of whole phrases and that the word finding is disturbed in these cases as a result of a certain breakdown of the "linear scheme of the phrase". We tried to discuss this process in a special paper (26) and we shall not dwell here on this very important problem. We are sure that further studies will help us to describe the mechanisms underlying this defect and to find objective cues which discern this ~~as~~ kind of naming defects from these we have already described.

The basic purpose of this short communication was to show that the process of naming has a very complex psychological structure and that the naming disturbances associated with "amnesic aphasia" can have a very different nature due to different underlying mechanisms.

We can only hope that further studies will bring our science to a better understanding of their mechanisms and that Neuro-psychology ~~and~~ will be able to come to a scientifically based ~~basis~~ analysis of naming defects and of the syndrome of the "amnesic apraxia".
